ABSTRACT

A circuit which accurately controls the word line (pass transistor gate) driving voltage to a 5 voltage which is both controlled and is not significantly greater than is needed to drive the word line. The elements of the present invention eliminate the need for a double-boot-strapping circuit, and ensure that no voltages exceed that necessary to fully turn on a memory cell access 10 transistor. Accordingly, voltages in excess of that which would reduce reliability are avoided, and accurate driving voltages are obtained. A DRAM is comprised of word lines, memory cells having enable inputs connected to the word lines, apparatus for 15 receiving word line selecting signals at first logic levels V_{ss} and V_{dd} , and for providing a select signal at levels V_{ss} and V_{dd} , a high voltage supply source $\boldsymbol{V}_{\text{pp}}$ which is higher in voltage than $\boldsymbol{V}_{\text{dd}},$ a circuit for translating the select signals at levels ${\rm V}_{\rm ss}$ and ${\rm V}_{\rm dd}$ 20 to levels V_{ss} and V_{pp} and for applying it directly to the word lines for application to the enable inputs whereby an above V_{dd} voltage level word line is achieved without the use of double boot-strap circuits. 25
